

daily from day 1 through day 28. The primary end point was the time to sustained alleviation of all signs and symptoms. Covid-19–related hospitalization and death from any cause were also

RESULTS

Among the 1296 participants who underwent randomization and were included in the full analysis population, 1288 received at least one dose of nirmatrelvir–ritonavir (654 participants) or placebo (634 participants) and had at least one postbaseline visit. The median time to sustained alleviation of all targeted signs and symptoms of Covid-19 was 12 days in the nirmatrelvir–ritonavir group and 13 days in the placebo group (P=0.60). Five participants (0.8%) in the nirmatrelvir–ritonavir group and 10 (1.6%) in the placebo group were hospitalized for Covid-19 or died from any cause (difference, -0.8 percentage points; 95% confidence interval, -2.0 to 0.4). The percentages of participants with adverse events were similar in the two groups (25.8% with nirmatrelvir–ritonavir and 24.1% with placebo). In the nirmatrelvir–ritonavir group, the most commonly reported treatment-related adverse events were dysgeusia (in 5.8% of the participants) and diarrhea (in 2.1%).

CONCLUSIONS

The time to sustained alleviation of all signs and symptoms of Covid-19 did not differ significantly between participants who received nirmatrelvir–ritonavir and those who received placebo. (Supported by Pfizer; EPIC-SR Clinical Trial; [NCT05011513](https://clinicaltrials.gov/ct2/show/study/NCT05011513).)

QUICK TAKE

Nirmatrelvir for Covid-19 Outpatients

2m 21s

Nirmatrelvir for

CLINICAL PROBLEM

Effective oral treatments for Covid-19 shorten the time to symptom resolution and reduce the risk of progression to severe illness. Nirmatrelvir, in combination with ritonavir, has been shown to reduce the risk of Covid-19 hospitalization or death from any cause in outpatients at high risk for severe Covid-19, but the duration of symptoms in a broader population remains unclear.

CLINICAL TRIAL

Design: A phase 2-3, double-blind, randomized controlled trial assessed the efficacy and safety of nirmatrelvir in adult outpatients (either unvaccinated or vaccinated) with severe Covid-19 and fully vaccinated outpatients at high risk for severe disease.

Intervention: 1296 adults with Covid-19 symptoms onset within the previous 5 days received either 300 mg of nirmatrelvir or placebo every 12 hours. The primary end point was the time to sustained alleviation of all targeted signs and symptoms.

RESULTS

Efficacy: The time to sustained alleviation of all targeted signs and symptoms did not differ significantly between groups.

Safety: The percentages of participants with adverse events through day 34 were similar in the two groups. The most common adverse events in the nirmatrelvir group were dysgeusia, diarrhea, and nausea.

LIMITATIONS AND REMAINING QUESTIONS

- The participants in the vaccinated group were enrolled regardless of the time since they received their last vaccine dose.
- Nirmatrelvir-ritonavir has a dysgeusia side effect, and participants may have suspected that they were receiving medication.
- The trial was started during the early phase of the pandemic, and therefore the results may not be generalizable to other variants of Covid-19.

Download a PDF

The current phase 2–3 trial evaluated the efficacy and safety of nirmatrelvir–ritonavir in non-symptomatic Covid-19 who either were at standard risk for severe Covid-19 (i.e., without risk factors for severe Covid-19, either unvaccinated or without vaccination within the previous 12 months) or were fully vaccinated. The primary end point was progression to severe Covid-19.

Methods

TRIAL DESIGN AND PARTICIPANTS

We conducted the Evaluation of Protease Inhibition for Covid-19 in Standard-Risk Patients in a double-blind, randomized, placebo-controlled trial to assess the efficacy, safety, and side effects of nirmatrelvir–ritonavir. Eligible participants were at least 18 years of age and had reverse-transcriptase–polymerase chain reaction (RT-PCR)–confirmed or rapid antigen–confirmed SARS-CoV-2 infection and associated signs or symptoms (Table S1 in the [Supplementary Appendix](#), available with the full text of this article at NEJM.org). Participants were required to have a prespecified Covid-19 sign or symptom on the day of randomization and to be capable of providing informed consent.

Patients with any predefined underlying condition associated with an increased risk of severe Covid-19 were eligible for participation if they had been fully vaccinated against Covid-19 (i.e., if they had received a Covid-19 vaccine authorized by the Food and Drug Administration for the treatment of Covid-19 in patients with risk factors for severe Covid-19).^{2–5} In addition, patients without underlying conditions associated with an increased risk of severe Covid-19 were eligible if they had not received a Covid-19 vaccine. After authorization by the Food and Drug Administration for the treatment of Covid-19 in patients with risk factors for severe Covid-19 in December 2021, the trial protocol was amended to exclude all patients with risk factors for severe Covid-19 (to maintain clinical balance) and to allow enrollment of patients without underlying conditions associated with an increased risk of severe Covid-19 who had not received a Covid-19 vaccine within the previous 12 months. Additional details are in the [Supplementary Appendix](#) and in the [protocol](#) (available at NEJM.org).

All participants provided written informed consent. The trial was conducted in accordance with the Declaration of Helsinki derived from international guidelines (see the [Supplementary Appendix](#)) and local laws and regulations. The protocol and other relevant documents were each approved by an institutional review board or ethics committee at each site before initiation. Nirmatrelvir and matching placebo were manufactured by Pfizer, and ritonavir tablets were manufactured by Hetero Labs and tested by Hetero Labs. Blinding was performed by Pfizer by means of overencapsulation.

Pfizer was responsible for the trial design and conduct and for data collection, analysis, and interpretation. A draft of the manuscript was written by medical writers (funded by Pfizer) under direction of the principal investigators. Data were available to the authors, who vouch for the accuracy and completeness of the data and its interpretation consistent with the protocol.

TRIAL PROCEDURES

After a screening period that lasted no longer than 48 hours, participants were randomly assigned to receive either nirmatrelvir–ritonavir (300 mg of nirmatrelvir and 100 mg of ritonavir) or placebo (consisting of inactive filler ingredients) every 12 hours for 5 days.

The prespecified key secondary end point was Covid-19–related hospitalization or death from Covid-19. Related secondary end points were the number of medical visits and the number of days in intensive care unit (ICU) related to Covid-19 through day 28. Viral load was evaluated as described previously (viral load assessed as at or above the lower limit of quantification or below the lower limit of quantification [$< 10^3$ copies per milliliter]). Viral load rebound was then evaluated on day 10 or day 14 and was defined either as a viral load of 10^3 copies per milliliter or higher on day 10 or day 14 in a patient with a viral load that had been below the lower limit of quantification on day 5 or as a viral load increase by at least $0.5 \log_{10}$ copies per milliliter from a viral load of 10^3 copies per milliliter or higher in a patient with a viral load that had been below the lower limit of quantification at day 5, day 10, or day 14. Symptom rebound was also evaluated and was defined as a return of symptoms (total symptom score increased by ≥ 4 points; scores range from 0 [no symptoms] to 10 [all symptoms]) after any abatement of symptoms.

SAFETY

The secondary objective was to describe the safety and side-effect profile of nirmatrelvir–ritonavir compared with placebo, with safety measured as the incidence of adverse events that emerged during the trial, all adverse events, and adverse events that led to discontinuation of nirmatrelvir–ritonavir or placebo. Safety was evaluated in the safety analysis population, which included all participants who received at least one dose of nirmatrelvir–ritonavir or placebo. The safety follow-up period lasted through day 34.

STATISTICAL ANALYSIS

Initially, we planned to enroll 1140 participants to ensure that 800 participants would be enrolled after symptom onset, which would provide 90% power to detect a 25% difference in the time to sustained alleviation of targeted Covid-19 signs and symptoms (8 days vs. 6 days), assuming that 18% of the participants would be lost to participation and that approximately 30% of the participants would undergo randomization after symptom onset. The protocol was later amended to include more participants to allow for a secondary efficacy end point (a composite of Covid-19–related hospitalization or death from Covid-19 28 days after enrollment).

The primary end point, the time to sustained alleviation of all Covid-19–related signs or symptoms, was compared between the groups with the use of a log-rank test. The median time to sustained alleviation was estimated with the Kaplan–Meier method within each group. For the key secondary end point, the cumulative incidence of participants who were hospitalized for Covid-19 or died during the first 28 days of the trial was estimated with the Kaplan–Meier method and was compared between the groups with the use of the Wald test. With 95% confidence intervals, the corresponding estimate of the standard error was computed with Greenwood's method. Covid-19–related medical visits through day 28 was compared between the groups with a negative binomial regression model. The mean number of days spent in the hospital in each group was summarized and compared with the bootstrap method with 100,000 replicates, with each replicate randomly selected (with replacement) from the set.

The primary end point was tested at a significance level of 0.05. If the results of this test were significant, 95% confidence intervals would be reported for secondary end points. These 95% confidence intervals

were women (54.0%), and the median age at enrollment was 42 years. Most participants were White (78.5%), and 41.4% identified as Hispanic or Latino; 48.6% had a body-mass index (BMI, the weight in kilograms divided by the square of the height in meters) of 25 or higher at screening (mean, 26.3). All the participants had confirmed SARS-CoV-2 infection, and 72.5% underwent randomization within 3 days after symptom onset. Slightly more than half the participants (56.9%) had received previous Covid-19 vaccination (most commonly with mRNA vaccines), and 49.9% had at least one risk factor for severe Covid-19; the most common risk factor was cigarette smoking (in 13.3% of the participants), and the most common coexisting condition was hypertension (in 12.3%). Eleven participants who had at least one risk factor and were unvaccinated were not included in the subgroup analyses. Adherence (defined as having taken 80 to 115% of tablets) was 94.8% in the nirmatrelvir–ritonavir group and 96.5% in the placebo group.

EFFICACY

Among the 1288 participants who received at least one dose of nirmatrelvir–ritonavir or placebo and had at least one postbaseline visit, the median time to sustained alleviation of all targeted Covid-19 signs or symptoms through day 28 was 12 days in the nirmatrelvir–ritonavir group and 13 days in the placebo group, a difference that was not significant ($P=0.60$) (Table 2). Similar results were observed in the high-risk subgroup (i.e., participants who had been vaccinated and had at least one risk factor for severe illness) and in the standard-risk subgroup (i.e., those who had no risk factors for severe illness and had never been vaccinated or had not been vaccinated within the previous 12 months).

A key secondary end point in the trial was Covid-19–related hospitalization or death from any cause (see Table S4 for data pertaining to this end point, including subgroup analyses). A total of 5 of the 654 participants (0.8%) who received nirmatrelvir–ritonavir and 10 of the 634 (1.6%) who received placebo were hospitalized for Covid-19 or died from any cause through day 28, which corresponded to a difference of -0.8 percentage points (95% confidence interval [CI], -2.0 to 0.4). One high-risk vaccinated participant in the placebo group died. None of the 5 participants in the nirmatrelvir–ritonavir group who were hospitalized were admitted to the ICU, whereas 3 of 10 participants in the placebo group were admitted to the ICU. In a planned subgroup analysis involving high-risk participants, hospitalization or death occurred in 3 (0.9%) in the nirmaltrelvir–ritonavir group and 7 (2.2%) in the placebo group (difference, -1.3 percentage points; 95% CI, -3.3 to 0.7).

* The full analysis population included participants who received the assigned intervention and had at least one postbaseline visit. Percentages may not total 100% because of rounding. † Race and ethnic group were reported for 632 participants. ‡ Data were missing for 2 participants. § Participants were considered to be high risk if they had at least one of the following risk factors: BMI ≥30, smoking, hypertension, diabetes mellitus, or age ≥65 yr. ¶ The most severe targeted sign or symptom was defined by the presence of such risk factors. †† Risk factors occurring in at least 10 participants.

Demographic and Clinical Characteristics of Participants In

group.

By day 14, viral load rebound had occurred in 4.3% of the participants in the nirmatrelvir–ritonavir group and 4.1% of those in the placebo group; symptom rebound occurred in 11.4% and 16.1%, respectively, and symptom and viral load rebound together occurred in 1.2% and 0.5%, respectively. Three participants with viral load rebound were hospitalized (one in the nirmatrelvir–ritonavir group and two in the placebo group), and there was a consistent temporal relationship between viral load rebound and hospitalization.

SAFETY

Adverse events that emerged during the treatment period, serious adverse events, and adverse events leading to discontinuation occurred in similar percentages of participants in the two groups (Table 3). The percentages of participants with adverse events of any cause during the treatment period were 25.8% in the nirmatrelvir–ritonavir group and 24.1% in the placebo group and did not differ markedly between vaccinated and unvaccinated participants. In the nirmatrelvir–ritonavir group, 24 participants (3.7%) reported grade 3 or 4 adverse events; the corresponding values in the placebo group were 25 (3.9%) and 1 (0.2%). Serious adverse events were reported by 8 participants (1.2%) receiving nirmatrelvir–ritonavir and by 12 (1.9%) receiving placebo. Of these events were considered by the investigator to be related to nirmatrelvir–ritonavir or placebo, respectively. The most common adverse events reported by nirmatrelvir–ritonavir recipients were dysgeusia (in 6.7% of the group) and diarrhea (in 4.0%), and nausea (in 3.1%); the corresponding percentages of placebo recipients with these events were 2.7%, 2.7%, and 2.7%, respectively.

A total of 83 participants (12.7%) had adverse events that were considered by the investigator to be related to nirmatrelvir–ritonavir, as compared with 31 (4.9%) with adverse events that were considered to be related to placebo; the difference was primarily due to higher percentages of participants in the nirmatrelvir–ritonavir group than in the placebo group having dysgeusia (5.8% vs. 0.2%) and diarrhea (2.1% vs. 1.3%). Adverse events and treatment-related adverse events of grade 3 or higher and all serious adverse events are summarized in Tables S5, S6, and S7.

TABLE 3

Table 3. Summary of Adverse Events

Adverse Event
Events that emerged during the treatment period
Any event
Serious event
Maximum event grade of 3 or higher
Maximum event grade of 5
Event leading to discontinuation of nirmatrelvir–ritonavir
Event leading to discontinuation of placebo; trial participation
Event leading to dose reduction of nirmatrelvir–ritonavir
Events related to nirmatrelvir–ritonavir
Any event
Serious event
Maximum event grade of 3 or higher
Maximum event grade of 5
Event leading to discontinuation of nirmatrelvir–ritonavir
Event leading to discontinuation of placebo; trial participation
Event leading to dose reduction of nirmatrelvir–ritonavir

* Safety was evaluated in the population that was vaccinated and had at least one postbaseline measurement. See Table for Grading the Severity of Adverse Events.
† A total of 323 events occurred in the nirmatrelvir–ritonavir group.
‡ A total of 109 treatment-related events occurred in the placebo group.

Discussion

criteria were studied. In four of the studies, most of the patient populations were vaccinated and received the administration of booster doses.^{12,14-16} The relative effectiveness of nirmatrelvir–ritonavir ranged from 53 to 76% when estimated without consideration of the time from symptom onset to recovery.^{12-14,16} Fewer Covid-19–related medical visits were also observed among participants receiving nirmatrelvir–ritonavir in the current trial.

The safety of nirmatrelvir–ritonavir in this trial is consistent with that in the EPIC-HR trial findings. Frequencies of adverse events that emerged during the treatment period, serious adverse events that led to discontinuation were similar in the two groups, with dysgeusia the most common adverse event among nirmatrelvir–ritonavir recipients, followed by diarrhea and nausea.

The limitations of the trial include the statistical analysis of the key secondary end point (time to hospitalization or death from any cause), which was only a descriptive analysis because the primary efficacy end point were not significant. Moreover, participants in the vaccinated high-risk group were enrolled irrespective of the time since their last administered dose of vaccine and irrespective of the time since their last vaccination on the efficacy of nirmatrelvir–ritonavir. Given the distinctive taste of nirmatrelvir–ritonavir, participants may have suspected that they were taking that medication, which may have limited the effectiveness of the medication. Another limitation is that the trial was started during the period of predominance of the B.1.1.7 variant, however, more recent real-world studies have provided evidence for the efficacy of nirmatrelvir–ritonavir against CoV-2 variants.¹⁰ As vaccine-induced immunity wanes, new variants emerge, and vaccination coverage is incomplete, the risk of severe Covid-19–associated outcomes among high-risk patients may increase. The strength of the trial is the enrollment of participants from diverse global locations, which enables generalizability of the findings. It is also important, since infections continue to occur even among persons with previous Covid-19.

In this trial, we assessed the safety and efficacy of nirmatrelvir–ritonavir as an antiviral agent in asymptomatic, nonhospitalized, vaccinated or unvaccinated adults. Nirmatrelvir–ritonavir was associated with a significantly shorter time to sustained alleviation of Covid-19 symptoms than placebo, and the efficacy of nirmatrelvir–ritonavir in patients who are not at high risk for severe Covid-19 has not been assessed.
